	3.7 0.1.1	28				
	3.8 0.1	28				
4	Roadmap to v1.0	29				

A drop-in replacement for django's ImageField that provides a flexible, intuitive and easily-extensible interface for quickly creating new images from the one assigned to your field.

In A Nutshell

- Creates images anywhere you need them: not just *in templates*.
- Non-destructive: Your original image is never modified.
- Sizer and Filter framework: enables you to quickly add new or modify existing ways to create new images:
 - Sizers create images with new sizes and/or aspect ratios
 - Filters change the appearance of an image
- Sizers can be chained onto Filters: Use case: give me a black-and-white, 400px by 400px square crop of this image.
- *Primary Point of Interest (PPOI) support*: provides a way to specify where the 'primary point of interest' of each individual image is a value which is available to all Sizers and Filters. Use case: sometimes you want the 'crop centerpoint' to be somewhere other than the center of an image. Includes *a user-friendly formfield/widget for selecting PPOI* in the admin (or anywhere else you use ModelForms).
- Works with any storage: Stores the images it creates within the same storage class as your field. Works great with external storage (like Amazon S3).
- *Fully interchangeable* with ImageField: you can easily remove VersatileImageField from your project's models whenever you'd like.
- Integrated caching: References to created images are stored in the cache, keeping your application running quickly and efficiently.
- *Django REST Framework support*: Serialize multiple image renditions from a single VersatileImageField.
- Flexible and fast: On-demand image creation can be toggled in your settings file allowing you to *turn it off* when you need your application to run as quickly as possible.

Table of Contents

2.1 Installation

Installation is easy with pip:

```
$ pip install django-versatileimagefield
```

2.1.1 Dependencies

- django>=1.5.0
- Pillow >= 2.4.0

django-versatileimagefield depends on the excellent Pillow fork of PIL. If you already have PIL installed, it is recommended you uninstall it prior to installing django-versatileimagefield:

```
$ pip uninstall PIL
$ pip install django-versatileimagefield
```

Note: django-versatileimagefield will not install django.

2.1.2 Settings

After installation completes, add 'versatileimagefield' to INSTALLED_APPS:

```
INSTALLED_APPS = (
    # All your other apps here
    'versatileimagefield',
)
```

VERSATILEIMAGEFIELD_SETTINGS

A dictionary that allows you to fine-tune how django-versatileimagefield works:

```
VERSATILEIMAGEFIELD_SETTINGS = {
    # The amount of time, in seconds, that references to created images
    # should be stored in the cache. Defaults to '2592000' (30 days)
    'cache_length': 2592000,
    # The name of the cache you'd like 'django-versatileimagefield' to use.
```

```
# Defaults to 'versatileimagefield_cache'. If no cache exists with the name
# provided, the 'default' cache will be used instead.
'cache_name': 'versatileimagefield_cache',
# The save quality of modified JPEG images. More info here:
# http://pillow.readthedocs.org/en/latest/handbook/image-file-formats.html#jpeg
# Defaults to 70
'jpeg_resize_quality': 70,
# A path on disc to an image that will be used as a 'placeholder'
# for non-existant images.
# If 'global_placeholder_image' is unset, the excellent, free-to-use
# http://placehold.it service will be used instead.
'global_placeholder_image': '/path/to/an-image.png',
# The name of the top-level folder within storage classes to save all
# sized images. Defaults to '___sized__'
'sized_directory_name': '__sized__',
# The name of the directory to save all filtered images within.
# Defaults to '___filtered__':
'filtered_directory_name': '__filtered__',
# Whether or not to create new images on-the-fly. Set this to 'False' for
# speedy performance but don't forget to 'pre-warm' to ensure they're
# created and available at the appropriate URL.
'create_images_on_demand': True
```

VERSATILEIMAGEFIELD_RENDITION_KEY_SETS

A dictionary used to specify 'Rendition Key Sets' that are used for both *serialization* or as a way to '*warm*' *image files* so they don't need to be created on demand (i.e. when settings.VERSATILEIMAGEFIELD_SETTINGS['create_images_on_demand'] is set to False) which will greatly improve the overall performance of your app. Here's an example:

```
VERSATILEIMAGEFIELD_RENDITION_KEY_SETS = {
    'image_gallery': [
        ('gallery_large', 'crop__800x450'),
        ('gallery_square_small', 'crop__50x50')
    1,
    'primary_image_detail': [
        ('hero', 'crop__600x283'),
        ('social', 'thumbnail__800x800')
    ],
    'primary_image_list': [
        ('list', 'crop__400x225'),
    ],
    'headshot': [
        ('headshot_small', 'crop__150x175'),
    ]
}
```

Each key in VERSATILEIMAGEFIELD_RENDITION_KEY_SETS signifies a 'Rendition Key Set', a list comprised of 2-tuples wherein the first position is a serialization-friendly name of an image rendition and the second position is a 'Rendition Key' (which dictates how the original image should be modified).

Writing Rendition Keys

Rendition Keys are intuitive and easy to write, simply swap out double-underscores for the dot-notated paths you'd use *in the shell* or *in templates*. Examples:

}

Intended	As 'Rendition	In the shell	In templates]
image	Key'			
400px by	'crop400x400	instance.image_field.cro	p[{'{400x400'].url	
400px Crop			instance.image_field.cro	p.400x400
			} }	
100px by	/thumbnail10	0xih0s0t'ance.image_field.thur	mb[m[ail['100x100'].url	
100px			instance.image_field.thu	mbnail.100x1
Thumbnail		'	} }	
Inverted Image	'filtersinve	rti'nstance.image_field.filt	teas.invert.url	
(Full Size)			instance.image_field.fil	ters.invert
		'	} }	
Inverted	'filtersinve	rti <u>ns</u> tramp <u>ce.</u> 50ma59@ <u>/</u> field.filt	tears.invert.crop['50x50']	url
Image, 50px			instance.image_field.fil	ters.invert.
by 50px crop			}}	

Using Rendition Key Sets

Rendition Key sets are useful! Read up on how they can help you...

- ... serializing VersatileImageField instances within Django REST Framework.
- ... 'warm' images to improve performance.

2.2 Model Integration

The centerpiece of django-versatileimagefield is its VersatileImageField which provides a simple, flexible interface for creating new images from the image you assign to it.

VersatileImageField extends django's ImageField and can be used as a drop-in replacement for it. Here's a simple example model that depicts a typical usage of django's ImageField:

```
# models.py with 'ImageField'
from django.db import models
class ImageExampleModel(models.Model):
    name = models.CharField(
       'Name',
       max_length=80
    )
    image = models.ImageField(
        'Image',
        upload_to='images/testimagemodel/',
        width_field='width',
        height_field='height'
    )
    height = models.PositiveIntegerField(
        'Image Height',
        blank=True,
        null=True
    )
    width = models.PositiveIntegerField(
        'Image Width',
        blank=True,
        null=True
    )
```

```
class Meta:
    verbose_name = 'Image Example'
    verbose_name_plural = 'Image Examples'
```

And here's that same model using VersatileImageField instead (see highlighted section in the code block below):

```
# models.py with 'VersatileImageField'
from django.db import models
```

from versatileimagefield.fields import VersatileImageField

```
class ImageExampleModel(models.Model):
    name = models.CharField(
       'Name',
        max_length=80
    )
    image = VersatileImageField(
        'Image',
        upload_to='images/testimagemodel/',
        width_field='width',
        height_field='height'
    )
    height = models.PositiveIntegerField(
        'Image Height',
        blank=True,
        null=True
    )
    width = models.PositiveIntegerField(
        'Image Width',
        blank=True,
        null=True
    )
    class Meta:
        verbose_name = 'Image Example'
        verbose_name_plural = 'Image Examples'
```

Note: VersatileImageField is fully interchangable with django.db.models.ImageField which means you can revert back to using django's ImageField anytime you'd like. It's fully-compatible with south so migrate to your heart's content!

2.3 Specifying a Primary Point of Interest (PPOI)

The *crop Sizer* is super-useful for creating images at a specific size/aspect-ratio however, sometimes you want the 'crop centerpoint' to be somewhere other than the center of a particular image. In fact, the initial inspiration for django-versatileimagefield came as a result of tackling this very problem.

The crop Sizer's core functionality (located in the versatileimagefield.versatileimagefield.CroppedImage.crop method) was inspired by PIL's ImageOps.fit function (by Kevin Cazabon) which takes an optional keyword argument, centering, that expects a 2-tuple comprised of floats which are greater than or equal to 0 and less than or equal to 1. These two values together form a cartesian coordinate system that dictates what percentage of pixels to 'trim' off each of the long sides (i.e. left/right or top/bottom, depending on the aspect ratio of the cropped size vs. the original size):

	Left	Center	Right
Тор	(0.0, 0.0)	(0.0, 0.5)	(0.0, 1.0)
Middle	(0.5, 0.0)	(0.5, 0.5)	(0.5, 1.0)
Bottom	(1.0, 0.0)	(1.0, 0.5)	(1.0, 1.0)

The crop Sizer works in a similar way but converts the 2-tuple into an exact (x, y) pixel coordinate which is then used as the 'centerpoint' of the crop. This approach gives significantly more accurate results than using ImageOps.fit, especially when dealing with PPOI values located near the edges of an image *or* aspect ratios that differ significantly from the original image.

Note: Even though the PPOI value is used as a crop 'centerpoint', the pixel it corresponds to won't necessarily be in the center of the cropped image, especially if its near the edges of the original image.

Note: At present, only the crop Sizer changes how it creates images based on PPOI but a VersatileImageField makes its PPOI value available to ALL its attached Filters and Sizers. Get creative!

2.3.1 The PPOIField

Each image managed by a VersatileImageField can store its own, unique PPOI in the database via the easy-to-use PPOIField. Here's how to integrate it into our example model (relevant lines highlighted in the code block below):

```
# models.py with 'VersatileImageField' & 'PPOIField'
from django.db import models
from versatileimagefield.fields import VersatileImageField, \
   PPOIField
class ImageExampleModel(models.Model):
    name = models.CharField(
        'Name',
        max_length=80
    )
    image = VersatileImageField(
        'Image',
        upload_to='images/testimagemodel/',
        width_field='width',
        height_field='height',
        ppoi_field='ppoi'
    )
    height = models.PositiveIntegerField(
        'Image Height',
        blank=True,
        null=True
    )
    width = models.PositiveIntegerField(
        'Image Width',
        blank=True,
        null=True
    )
    ppoi = PPOIField(
        'Image PPOI'
    )
    class Meta:
```

verbose_name = 'Image Example'
verbose_name_plural = 'Image Examples'

As you can see, you'll need to add a new PPOIField field to your model and then include the name of that field in the VersatileImageField's ppoi_field keyword argument. That's it!

Note: **PPOIField** is fully-compatible with south so migrate to your heart's content!

How PPOI is Stored in the Database

The **Primary Point of Interest** is stored in the database as a string with the x and y coordinates limited to two decimal places and separated by an 'x' (for instance: '0.5x0.5' or '0.62x0.28').

2.3.2 Setting PPOI

PPOI is set via the ppoi attribute on a VersatileImageField. You should **always** set an image's PPOI here (as opposed to directly on a PPOIField attribute) since a VersatileImageField will ensure updated values are passed-down to all its attached Filters & Sizers.

When you save a model instance, VersatileImageField will ensure its currently-assigned PPOI value is 'sent' to the PPOIField associated with it (if any) prior to writing to the database.

Via The Shell

```
# Importing our example Model
>>> from someapp.models import ImageExampleModel
# Retrieving a model instance
>>> example = ImageExampleModel.objects.all()[0]
# Retrieving the current PPOI value associated with the image field
# A `VersatileImageField`'s PPOI value is ALWAYS associated with the `ppoi`
# attribute, irregardless of what you named the 'PPOIField' attribute on your model
>>> example.image.ppoi
(0.5, 0.5)
# Creating a cropped image
>>> example.image.crop['400x400'].url
u'/media/___sized__/images/testimagemodel/test-image-crop-c0-5__0-5-400x400.jpg'
# Changing the PPOI value
>>> example.image.ppoi = (1, 1)
# Creating a new cropped image with the new PPOI value
>>> example.image.crop['400x400'].url
u'/media/___sized__/images/testimagemodel/test-image-crop-c1__1-400x400.jpg'
# PPOI values can be set as either a tuple or a string
>>> example.image.ppoi = '0.1x0.55'
>>> example.image.ppoi
(0.1, 0.55)
>>> example.image.ppoi = (0.75, 0.25)
>>> example.image.crop['400x400'].url
u'/media/__sized__/images/testimagemodel/test-image-crop-c0-75__0-25-400x400.jpg'
# u'0.75x0.25' is written to the database in the 'ppoi' column associated with
# our example model
>>> example.save()
```

As you can see, changing an image's PPOI changes the filename of the cropped image. This ensures updates to a VersatileImageField's PPOI value will result in unique cache entries for each unique image it creates.

Note: Each time a field's PPOI is set, its attached Filters & Sizers will be immediately updated with the new value.

2.3.3 FormField/Admin Integration

It's pretty hard to accurately set a particular image's PPOI when working in the Python shell so django-versatileimagefield ships with an admin-ready formfield. Simply add an image, click 'Save and continue editing', click where you'd like the PPOI to be and then save your model instance again. A helpful translucent red square will indicate where the PPOI value is currently set to on the image:

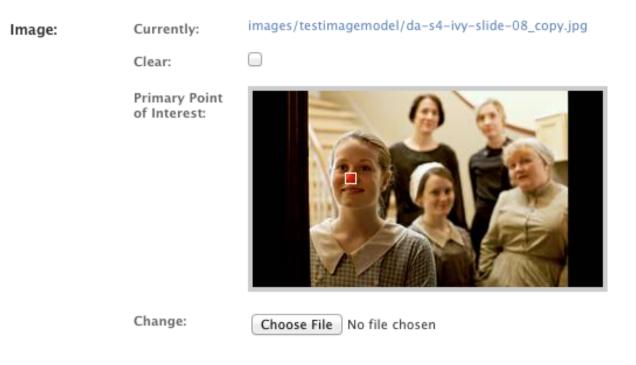

Figure 2.1: django-versatileimagefield PPOI admin widget example

2.4 Using Sizers and Filters

Where VersatileImageField shines is in its ability to create new images on the fly via its Sizer & Filter frame-work.

2.4.1 Sizers

Sizers provide a way to create new images of differing sizes from the one assigned to the field. VersatileImageField ships with two Sizers, thumbnail and crop.

Each Sizer registered to the *Sizer registry* is available as an attribute on each VersatileImageField. Sizers are dict subclasses that only accept precisely formatted keys comprised of two integers – representing width and height, respectively – separated by an 'x' (i.e. ['400x400']). If you send a malformed/invalid key to a Sizer, a MalformedSizedImageKey exception will raise.

Included Sizers

thumbnail

Here's how you would create a thumbnail image that would be constrained to fit within a 400px by 400px area:

```
# Importing our example Model
>>> from someapp.models import ImageExampleModel
# Retrieving a model instance
>>> example = ImageExampleModel.objects.all()[0]
# Displaying the path-on-storage of the image currently assigned to the field
>>> example.image.name
u'images/testimagemodel/test-image.jpg'
# Retrieving the path on the field's storage class to a 400px wide
# by 400px tall constrained thumbnail of the image.
>>> example.image.thumbnail['400x400'].name
u'_sized_/images/testimagemodel/test-image-thumbnail-400x400.jpg'
# Retrieving the URL to the 400px wide by 400px tall thumbnail
>>> example.image.thumbnail['400x400'].url
u'/media/_sized_/images/testimagemodel/test-image-thumbnail-400x400.jpg'
```

Note: Images are created on-demand. If no image had yet existed at the location required – by either the path (.name) *or* URL (.url) shown in the highlighted lines above – one would have been created directly before returning it.

Here's how you'd open the thumbnail image we just created as an image file directly in the shell:

crop

To create images cropped to a specific size, use the crop Sizer:

```
# Retrieving the URL to a 400px wide by 400px tall crop of the image
>>> example.image.crop['400x400'].url
u'/media/__sized_/images/testimagemodel/test-image-crop-c0-5__0-5-400x400.jpg'
```

The crop Sizer will first scale an image down to its longest side and then crop/trim inwards, centered on the **Primary Point of Interest** (PPOI, for short). For more info about what PPOI is and how it's used see the *Specifying a Primary Point of Interest* (*PPOI*) section.

How Sized Image Files are Named/Stored All Sizers subclass from versatileimagefield.datastructures.sizedimage which uses a unique-to-size-specified string – provided via its get_filename_key() method – that is included in the filename of each image it creates.

Note: The thumbnail Sizer simply combines 'thumbnail' with the size key passed (i.e. '400x400') while the crop Sizer combines 'crop', the field's PPOI value (as a string) and the size key passed; all Sizer 'filename keys' begin and end with dashes '-' for readability.

All images created by a Sizer are stored within the field's storage class in a top-level folder named '___sized__', maintaining the same descendant folder structure as the original image. If you'd like to change the name of this folder to something other than '___sized__', adjust the value of VERSATILEIMAGEFIELD_SETTINGS['sized_directory_name'] within your settings file.

Sizers are quick and easy to write, for more information about how it's done, see the Writing a Custom Sizer section.

2.4.2 Filters

Filters create new images that are the same size and aspect ratio as the original image.

Included Filters

invert

The invert filter will invert the color palette of an image:

```
# Importing our example Model
>>> from someapp.models import ImageExampleModel
# Retrieving a model instance
>>> example = ImageExampleModel.objects.all()[0]
# Returning the path-on-storage to the image currently assigned to the field
>>> example.image.name
u'images/testimagemodel/test-image.jpg'
# Displaying the path (within the field's storage class) to an image
# with an inverted color pallete from that of the original image
>>> example.image.filters.invert.name
u'images/testimagemodel/__filtered__/test-image__invert__.jpg'
# Displaying the URL to the inverted image
>>> example.image.filters.invert.url
u'/media/images/testimagemodel/__filtered__/test-image__invert__.jpg'
```

As you can see, there's a filters attribute available on each VersatileImageField which contains all filters currently registered to the Filter registry.

Using Sizers with Filters

What makes Filters extra-useful is that they have access to all registered Sizers:

```
# Creating a thumbnail of a filtered image
>>> example.image.filters.invert.thumbnail['400x400'].url
u'/media/__sized__/images/testimagemodel/__filtered__/test-image__invert___thumbnail-400x400.jpg'
# Creating a crop from a filtered image
>>> example.image.filters.invert.crop['400x400'].url
u'/media/__sized__/images/testimagemodel/__filtered__/test-image__invert__-c0-5__0-5-400x400.jpg'
```

Note: Filtered images are created the first time they are directly accessed (by either evaluating their name/url attributes or by accessing a Sizer attached to it). Once created, a reference is stored in the cache for each created image which makes for speedy subsequent retrievals.

How Filtered Image Files are Named/Stored

All Filters subclass from versatileimagefield.datastructures.filteredimage.FilteredImage which provides a get_filename_key() method that returns a unique-to-filter-specified string – surrounded by double underscores, i.e. '__invert__' – which is appended to the filename of each image it creates.

All images created by a Filter are stored within a folder named ___filtered__ that sits in the same directory as the original image. If you'd like to change the name of this folder to something other than 'filtered', adjust the value of VERSATILEIMAGEFIELD_SETTINGS['filtered_directory_name'] within your settings file.

Filters are quick and easy to write, for more information about creating your own, see the *Writing a Custom Filter* section.

2.4.3 Using Sizers / Filters in Templates

Template usage is straight forward and easy since both attributes and dictionary keys can be accessed via dot-notation; no crufty templatetags necessary:

```
<!-- Sizers -->
<img src="{{ instance.image.thumbnail.400x400 }}" />
<img src="{{ instance.image.crop.400x400 }}" />
<!-- Filters -->
<img src="{{ instance.image.filters.invert.url }}" />
<!-- Filters + Sizers -->
<img src="{{ instance.image.filters.invert.thumbnail.400x400 }}" />
<img src="{{ instance.image.filters.invert.crop.400x400 }}" />
```

Note: Using the url attribute on Sizers is optional in templates. Why? All Sizers return an instance of versatileimagefield.datastructures.sizedimage.SizedImageInstance which provides the sized image's URL via the __unicode__() method (which django's templating engine looks for when asked to render class instances directly).

2.5 Writing Custom Sizers and Filters

It's quick and easy to create new Sizers and Filters for use on your project's VersatileImageField fields or *modify already-registered Sizers and Filters*.

Both Sizers and Filters subclass from versatileimagefield.datastructures.base.ProcessedImage which provides a *preprocessing API* as well as all the business logic necessary to retrieve and save images.

The 'meat' of each Sizer & Filter – a.k.a what actually modifies the original image – takes place within the process_image method which all subclasses must define (not doing so will raise a NotImplementedError). Sizers and Filters expect slightly different keyword arguments (Sizers required width and height, for example) see below for specifics:

2.5.1 Writing a Custom Sizer

All Sizers should subclass versatileimagefield.datastructures.sizedimage.SizedImage and, at a minimum, MUST do two things:

- Define either the filename_key attribute or override the get_filename_key() method which is necessary for creating unique-to-Sizer-and-size-specified filenames. If neither of the aforementioned is done a NotImplementedError exception will be raised.
- 2. Define a process_image method that accepts the following arguments:
 - image: a PIL Image instance

- image_format: A valid image mime type (e.g. 'image/jpeg'). This is provided by the create_resized_image method (which calls process_image).
- save_kwargs: A dict of any keyword arguments needed by PIL's Image.save method (initially provided by the pre-processing API).
- width: An integer representing the width specified by the user in the size key.
- height: An integer representing the height specified by the user in the size key.

For an example, let's take a look at the thumbnail Sizer (versatileimagefield.versatileimagefield.ThumbnailIma

```
from PIL import Image
from .datastructures import SizedImage
class ThumbnailImage(SizedImage):
    .....
    Sizes an image down to fit within a bounding box
    See the 'process_image() ' method for more information
    filename_key = 'thumbnail'
    def process_image(self, image, image_format, save_kwargs,
                      width, height):
        .....
        Returns a StringIO instance of 'image' that will fit
        within a bounding box as specified by 'width'x 'height'
        .....
        imagefile = StringIO.StringIO()
        image.thumbnail(
            (width, height),
            Image.ANTIALIAS
        )
        image.save(
            imagefile,
            **save_kwargs
        )
        return imagefile
```

Important: process_image should *always* return a *StringIO* instance. See *What process_image should return* for more information.

2.5.2 Writing a Custom Filter

import StringIO

All Filters should subclass versatileimagefield.datastructures.filteredimage.FilteredImage and only need to define a process_filter method with following arguments:

- image: a PIL Image instance
- image_format: A valid image mime type (e.g. 'image/jpeg'). This is provided by the create_resized_image() method (which calls process_image).
- save_kwargs: A dict of any keyword arguments needed by PIL's Image.save method (initially provided by the pre-processing API).

For an example, let's take a look at the invert Filter (versatileimagefield.versatileimagefield.InvertImage):

```
import StringIO
from PIL import ImageOps
from .datastructures import FilteredImage
class InvertImage (FilteredImage):
    .....
    Inverts the colors of an image.
    See the 'process_image() ' for more specifics
    .....
    def process_image(self, image, image_format, save_kwargs={}):
        .....
        Returns a StringIO instance of 'image' with inverted colors
        .....
        imagefile = StringIO.StringIO()
        inv_image = ImageOps.invert(image)
        inv_image.save(
            imagefile,
            **save_kwargs
        )
        return imagefile
```

Important: process_image should always return a StringIO instance. See *What process_image should return* for more information.

2.5.3 What process_image should return

Any process_image method you write should *always* return a StringIO instance comprised of raw image data. The actual image file will be written to your field's storage class via the save_image method. Note how save_kwargs is passed into PIL's Image.save method in the examples above, this ensures PIL knows how to write this data (based on mime type or any other per-filetype specific options provided by the *preprocessing API*).

2.5.4 The Pre-processing API

Both Sizers and Filters have access to a pre-processing API that provides hooks for doing any per-mime-type processing. This allows your Sizers and Filters to do one thing for JPEGs and another for GIFs, for instance. One example of this is in how Sizers 'know' how to preserve transparency for GIFs or save JPEGs as RGB (at the user-defined quality):

```
# versatileimagefield/datastructures/sizedimage.py
class SizedImage(ProcessedImage, dict):
    "<a bunch of ommited code here>"
    def preprocess_GIF(self, image, **kwargs):
        """
        Receives a PIL Image instance of a GIF and returns 2-tuple:
            * [0]: Original Image instance (passed to 'image')
            * [1]: Dict with a transparency key (to GIF transparency layer)
        """
        return (image, {'transparency': image.info['transparency']})
```

All pre-processors should accept one required argument image (A PIL Image instance) and **kwargs (for easy extension by subclasses) and return a 2-tuple of the image and a dict of any additional keyword arguments to pass along to PIL's Image.save method.

Pre-processor Naming Convention

In order for preprocessor methods to run, they need to be named correctly via this simple naming convention: preprocess_FILETYPE. Here's a list of all currently-supported file types:

- BMP
- DCX
- EPS
- GIF
- JPEG
- PCD
- PCX
- PDF
- PNG
- PPM
- PSD
- TIFF
- XBM
- XPM

So, if you'd want to write a PNG-specific preprocessor, your Sizer or Filter would need to define a method named preprocess_PNG.

Note: I've only tested VersatileImageField with PNG, GIF and JPEG files; the list above is what PIL supports, for more information about per filetype support in PIL visit here.

2.5.5 Registering Sizers and Filters

Registering Sizers and Filters is easy and straight-forward; if you've ever registered a model with django's admin you'll feel right at home.

django-versatileimagefield finds Sizers & Filters within modules named versatileimagefield – (i.e. versatileimagefield.py) that are available at the 'top level' of each app on INSTALLED_APPS.

Here's an example:

After defining your Sizers and Filters you'll need to register them with the versatileimagefield_registry. Here's how the ThumbnailSizer is registered (see the highlighted lines in the following code block for the relevant bits):

```
# versatileimagefield/versatileimagefield.py
import StringIO
```

from PIL import Image

```
from .datastructures import SizedImage
from .registry import versatileimagefield_registry
```

```
class ThumbnailImage(SizedImage):
    .....
    Sizes an image down to fit within a bounding box
    See the 'process_image() ' method for more information
    .....
    filename_key = 'thumbnail'
    def process_image(self, image, image_format, save_kwargs,
                      width, height):
        .....
        Returns a StringIO instance of 'image' that will fit
        within a bounding box as specified by 'width'x 'height'
        .....
        imagefile = StringIO.StringIO()
        image.thumbnail(
            (width, height),
            Image.ANTIALIAS
        )
        image.save(
            imagefile,
            **save_kwargs
        )
        return imagefile
# Registering the ThumbnailSizer to be available on VersatileImageField
# via the 'thumbnail' attribute
versatileimagefield_registry.register_sizer('thumbnail', ThumbnailImage)]
```

All Sizers are registered via the versatileimagefield_registry.register_sizer method. The first argument is the attribute you want to make the Sizer available at and the second is the SizedImage subclass.

Filters are just as easy. Here's how the InvertImage filter is registered (see the highlighted lines in the following code block for the relevant bits):

```
import StringIO
from PIL import ImageOps
from .datastructures import FilteredImage
from .registry import versatileimagefield_registry
class InvertImage(FilteredImage):
    .....
    Inverts the colors of an image.
    See the 'process_image() ' for more specifics
    .....
    def process_image(self, image, image_format, save_kwargs={}):
        .....
        Returns a StringIO instance of 'image' with inverted colors
        .....
        imagefile = StringIO.StringIO()
        inv_image = ImageOps.invert(image)
        inv_image.save(
            imagefile,
            **save_kwargs
        )
        return imagefile
```

versatileimagefield_registry.register_filter('invert', InvertImage)

All Filters are registered via the versatileimagefield_registry.register_filter method. The first argument is the attribute you want to make the Filter available at and the second is the FilteredImage subclass.

Unallowed Sizer & Filter Names

Sizer and Filter names cannot begin with an underscore as it would prevent them from being accessible within the template layer. Additionally, since Sizers are available for use directly on a VersatileImageField, there are some Sizer names that are unallowed; trying to register a Sizer with one of the following names will result in a UnallowedSizerName exception:

- build_filters_and_sizers
- chunks
- close
- closed
- create_on_demand
- delete
- encoding
- field
- file
- fileno
- filters

- flush
- height
- instance
- isatty
- multiple_chunks
- name
- newlines
- open
- path
- ppoi
- read
- readinto
- readline
- readlines
- save
- seek
- size
- softspace
- storage
- tell
- truncate
- url
- validate_ppoi
- width
- write
- writelines
- xreadlines

2.5.6 Overriding an existing Sizer or Filter

If you try to register a Sizer or Filter with an attribute name that's already in use (like crop or thumbnail or invert), an AlreadyRegistered exception will raise.

Caution: A Sizer can have the same name as a Filter (since names are only required to be unique per type) however it's **not** recommended.

If you'd like to override an already-registered Sizer or Filter just use either the unregister_sizer or unregister_filter methods of versatileimagefield_registry. Here's how you could 'override' the crop Sizer:

```
from versatileimagefield.registry import versatileimagefield_registry
```

```
# Unregistering the 'crop' Sizer
versatileimagefield_registry.unregister_sizer('crop')
# Registering a custom 'crop' Sizer
versatileimagefield_registry.register_sizer('crop', SomeCustomSizedImageCls)
```

The order that Sizers and Filters register corresponds to their containing app's position on INSTALLED_APPS. This means that if you want to override one of the default Sizers or Filters your app needs to be included after 'versatileimagefield':

2.6 Django REST Framework Integration

If you've got an API powered by Tom Christie's excellent Django REST Framework and want to serve images in multiple sizes/renditions django-versatileimagefield has you covered with it's VersatileImageFieldSerializer.

2.6.1 Example

To demonstrate how it works we'll use this simple model:

```
# myproject/person/models.py
```

```
from django.db import models
```

from versatileimagefield.fields import VersatileImageField, PPOIField

```
class Person(models.Model):
    """Represents a person."""
    name_first = models.CharField('First Name', max_length=80)
    name_last = models.CharField('Last Name', max_length=100)
    headshot = VersatileImageField(
         'Headshot',
         upload_to='headshots/',
         ppoi_field='headshot_ppoi'
    )
    headshot_ppoi = PPOIField()
class Meta:
        verbose_name = 'Person'
        verbose_name_plural = 'People'
```

OK, let's write a simple ModelSerializer subclass to serialize Person instances:

```
# myproject/person/serializers.py
from rest_framework import serializers
```

from versatileimagefield.serializers import VersatileImageFieldSerializer

```
from .models import Person
```

And here's what it would look like serialized:

'headshot'

)

```
>>> from myproject.person.models import Person
>>> john_doe = Person.objects.create(
    name_first='John',
. . .
       name_last='Doe',
. . .
       headshot='headshots/john_doe_headshot.jpg'
. . .
. . . )
>>> john_doe.save()
>>> from myproject.person.serializers import PersonSerializer
>>> john_doe_serialized = PersonSerializer(john_doe)
>>> john_doe_serialized.data
    'name_first': 'John',
    'name_last': 'Doe',
    'headshot': {
        'full_size': '/media/headshots/john_doe_headshot.jpg',
        'thumbnail': '/media/headshots/john_doe_headshot-thumbnail-400x400.jpg',
        'medium_square_crop': '/media/headshots/john_doe_headshot-crop-c0-5__0-5-400x400.jpg',
        'small_square_crop': '/media/headshots/john_doe_headshot-crop-c0-5__0-5-50x50.jpg',
    }
}
```

As you can see, the sizes argument on VersatileImageFieldSerializer simply unpacks the list of 2tuples using the value in the first position as the attribute of the image and the second position as a 'Rendition Key' which dictates how the original image should be modified.

Reusing Rendition Key Sets

It's common to want to re-use similar sets of images across models and fields so django-versatileimagefield provides a setting, VERSATILEIMAGEFIELD_RENDITION_KEY_SETS for defining them (*docs*).

Let's move the Rendition Key Set we used above into our settings file:

```
# myproject/settings.py
VERSATILEIMAGEFIELD_RENDITION_KEY_SETS = {
    'person_headshot': [
        ('full_size', 'url'),
        ('thumbnail', 'thumbnail__100x100'),
        ('medium_square_crop', 'crop__400x400'),
        ('small_square_crop', 'crop__50x50')
    ]
}
```

Now, let's update our serializer to use it:

```
# myproject/person/serializers.py
from rest_framework import serializers
from versatileimagefield.serializers import VersatileImageFieldSerializer
from .models import Person
class PersonSerializer(serializers.ModelSerializer):
    """Serializes Person instances"""
   headshot = VersatileImageFieldSerializer(
        sizes='person_headshot'
    )
    class Meta:
        model = Person
        fields = (
            'name_first',
            'name_last',
            'headshot'
        )
```

That's it! Now that you know how to define Rendition Key Sets, leverage them to improve performance!

2.7 Improving Performance

During development, VersatileImageField's *on-demand image creation* enables you to quickly iterate but, once your application is deployed, this convenience adds a small bit of overhead that you'll probably want to turn off once your app is in production.

2.7.1 Turning off on-demand image creation

To turn off on-demand image creation just set the 'create_images_on_demand' key of the VERSATILEIMAGEFIELD_SETTINGS setting to False (*docs*). Now your VersatileImageField fields will return URLs to images without first checking to see if they've actually been created yet.

Note: Once an image has been created by a VersatileImageField, a reference to it is stored in the cache which makes for speedy subsequent retrievals. Setting VERSATILEIMAGEFIELD_SETTINGS['create_images_on_demand'] to False bypasses this entirely making VersatileImageField perform even faster (*docs*).

2.7.2 Ensuring images are created

This boost in performance is great but now you'll need to ensure that the images your application links to actually exist. Luckily, VersatileImageFieldWarmer will help you do just that. Here's an example in the Python shell using the *example model* from the Django REST Framework serialization example:

```
>>> from myproject.person.models import Person
>>> from versatileimagefield.image_warmer import VersatileImageFieldWarmer
>>> person_img_warmer = VersatileImageFieldWarmer(
... instance_or_queryset=Person.objects.all(),
... rendition_key_set='person_headshot',
... image_attr='headshot',
... verbose=True
... )
>>> num_created, failed_to_create = person_img_warmer.warm()
```

num_created will be an integer of how many images were successfully created and failed_to_create will be a list of paths to images (on the field's storage class) that could not be created (due to a PIL/Pillow error, for example).

This technique is useful if you've recently converted your project's models.ImageField fields to use VersatileImageField or if you want to 'pre warm' images as part of a Fabric script.

Note: The above example would create a set of images (as dictated by the 'person_headshot' *Rendition Key Set*) for the headshot field of each Person instance. rendition_key_set also accepts a valid *Rendition Key Set* directly:

```
>>> person_img_warmer = VersatileImageFieldWarmer(
        instance_or_queryset=Person.objects.all(),
. . .
        rendition_key_set=[
. . .
             ('large_horiz_crop', '1200x600'),
. . .
             ('large_vert_crop', '600x1200'),
. . .
        ],
. . .
        image_attr='headshot',
. . .
        verbose=True
. . .
...)
```

Note: Setting verbose=True when instantiating a VersatileImageFieldWarmer will display a yum-style progress bar showing the image warming progress:

Note: The image_attr argument can be dot-notated in order to follow ForeignKey and OneToOneField relationships. Example: 'related_model.headshot'.

Auto-creating sets of images on post_save

You also might want to create new images immediately after model instances are saved. Here's how we'd do it with our example model (see highlighted lines below):

myproject/person/models.py

```
from django.db import models
from django.dispatch import receiver
```

```
from versatileimagefield.image_warmer import VersatileImageFieldWarmer
class Person(models.Model):
    """Represents a person."""
   name_first = models.CharField('First Name', max_length=80)
    name_last = models.CharField('Last Name', max_length=100)
   headshot = VersatileImageField(
       'Headshot',
       upload_to='headshots/',
       ppoi_field='headshot_ppoi'
    )
   headshot_ppoi = PPOIField()
   class Meta:
       verbose_name = 'Person'
       verbose_name_plural = 'People'
@receiver(models.signals.post_save, sender=Person)
def warm_Person_headshot_images(sender, instance, **kwargs):
    """Ensures Person head shots are created post-save"""
   person_img_warmer = VersatileImageFieldWarmer(
        instance_or_queryset=instance,
        rendition_key_set='person_headshot',
        image_attr='headshot'
    )
    num_created, failed_to_create = person_img_warmer.warm()
```

from versatileimagefield.fields import VersatileImageField, PPOIField

Release Notes

3.1 0.2.1

• Ensuring *admin widget*-dependent thumbnail images are created even if VERSATILEIMAGEFIELD_SETTINGS['create_on_demand'] is set to False

3.2 0.2

- Introducing Django REST Framework support!
- Added ability to turn off on-demand image creation and pre-warm images to improve performance.

3.3 0.1.5

• Squashed CroppedImage bug that was causing black stripes to appear on crops of images with PPOI values that were to the right and/or bottom of center (greater-than 0.5).

3.4 0.1.4

- Overhauled how CroppedImage processes PPOI value when creating cropped images. This new approach yields significantly more accurate results than using the previously utilized ImageOps.fit function, especially when dealing with PPOI values located near the edges of an image *or* aspect ratios that differ significantly from the original image.
- Improved PPOI validation
- Squashed unset VERSATILEIMAGEFIELD_SETTINGS['global_placeholder_image'] bug.
- Set crop Sizer default resample to PIL.Image.ANTIALIAS

3.5 0.1.3

- Added support for auto-rotation during pre-processing as dictated by 'Orientation' EXIF data, if available.
- · Added release notes to docs

3.6 0.1.2

• Removed redundant javascript from ppoi 'click' widget (thanks, @skumar!)

3.7 0.1.1

- Converted giant README into Sphinx-friendly RST
- Docs added to readthedocs

3.8 0.1

• Initial open source release

Roadmap to v1.0

- Tests!
- Python 3 support
- Custom placeholder image docs
- Programmatically delete images created by VersatileImageField (including clearing their connected cache keys)
